

**analytic** /æˈnəlɪtɪk/ (analytical) means the same as **analytical**. [mainly AM]

**analytical** /æˈnəlɪtɪkəl/ **ADJ** **1** An analytical way of doing something involves the use of logical reasoning. **□** I have an analytical approach to every survey. **♦** **analytically** /æˈnəlɪtɪkli/ **ADV** A teacher can encourage children to think analytically. **2** Analytical research involves using chemical analysis. **□** All raw materials are subjected to our latest analytical techniques.

**analyze** /æˈnəlaɪz/ → see **analyse**.

**anarchic** /æˈnɑːrkiːk/ If you describe someone or something as **anarchic**, you disapprove of them because they do not recognize or obey any rules or laws. **□** ...anarchic attitudes and complete disrespect for authority.

**anarchism** /æˈnɑːrkɪzəm/ **N-UNCOUNT** Anarchism is the belief that the laws and power of governments should be replaced by people working together freely.

**anarchist** /æˈnɑːkɪst/ (**anarchists**) **1** An anarchist is a person who believes in anarchism. **□** ...a well-known anarchist poet. **2** If someone has anarchist beliefs or views, they believe in anarchism. **□** He was apparently quite converted from his anarchist views. **3** If you say that someone is an anarchist, you disapprove of them because they seem to pay no attention to the rules or laws that everyone else obeys. **□** He was a social anarchist.

**anarchistic** /æˈnɑːkɪstɪk/ **1** An anarchistic person believes in anarchism. **Anarchistic** activity or literature promotes anarchism. **□** ...an anarchistic revolutionary movement. **2** If you describe someone as **anarchistic**, you disapprove of them because they pay no attention to the rules or laws that everyone else obeys. **□** The Hell's Angels were once the most notorious and anarchistic of motorbike gangs.

**anarcho-** /æˈnɑːrkoʊ-/ **COMB in ADJ and N** **Anarcho-** combines with nouns and adjectives to form words indicating that something is both anarchistic and the other thing that is mentioned. **□** In France there was a long tradition of anarcho-syndicalism.

**anarchy** /æˈnɑːki/ If you describe a situation as **anarchy**, you mean that nobody seems to be paying any attention to rules or laws. **□** Civil war and famine sent the nation plunging into anarchy.

**anathema** /əˈnæθəmə/ If something is **anathema** to you, you strongly dislike it. **□** Violence was anathema to them.

**anatomical** /æˈnətomɪkəl/ **ADJ** **Anatomical** means relating to the structure of the bodies of people and animals. **□** ...minute anatomical differences between insects. **♦** **anatomically** /æˈnətomɪkli/ **ADV** I need my pictures to be anatomically correct.

**anatomist** /əˈnætəmist/ (**anatomists**) **N-COUNT** An anatomist is an expert in anatomy.

**anatomize** /əˈnætəmaɪz/ (**anatomizes, anatomizing, anatomized**)

**✓** in BRIT, also use **anatomise**

A *stable* sorting algorithm is one that keeps the original order of any pair of items that have equivalent keys.

KC JH 9S 8C 7D 4S 3H

A stable sorting algorithm, now sorting by suit in order  $S < H < C < D$  will give

9S 4S JH 3H KC 8C 7D

Let  $x_0, x_1, x_2, \dots, x_n$  be the items in the list in original order.

Let the key for item  $x_i$  be  $x_i.k$ , and now re-sort the list by the key.

Let  $p(x_i)$  be the position of  $x_i$  in the resorted list.

The sorting algorithm is *stable*

if and only if

for any pair  $(i, j)$  where  $x_i.k == x_j.k$  and  $i < j$ , then  $p(x_i) < p(x_j)$

Which of our previous algorithms (as written) are stable?

Bubblesort	yes
------------	-----

Selectionsort	no

## Lexicographic order

For two strings of characters, add a sequence of 'a' characters to the end of the smaller, so that they are the same length.

string  $s$  is *lexicographically before*  $t$  if and only if

$s[0] < t[0]$ , or

$s[0] == t[0]$  and  $s[1] < t[1]$ , or

$s[0] = t[0]$ ,  $s[1] == t[1]$ , and  $s[2] < t[2]$ , or

...

string  $s$  is *lexicographically before*  $t$

if and only if

$\exists i \geq 0$  s.t.  $\forall j < i$   $s[j] == t[j]$  and  $s[i] < t[i]$

Exercise: write an algorithm to sort a list of tuples in lexicographic order, but where we only compare one element of each tuple on each pass?

[(4,1), (5,7), (3,2), (7,2), (6,4), (9,3), (9,2), (7,1), (5,4)]

Answer?

Choose any stable sorting algorithm.

1. Sort by 2<sup>nd</sup> elt
2. Re-sort by 1<sup>st</sup> elt

Applying this technique using Bucket Sort is called *Radix* sort.

[(4,1), (5,7), (3,2), (7,2), (6,4), (9,3), (9,2), (7,1), (5,4), (4,5)]

Sort the list using Bucket sort on the 2<sup>nd</sup> element

[(4,1), (7,1), (3,2), (7,2), (9,2), (9,3), (6,4), (5,4), (4,5), (5,7)]

Now sort the list again using Bucket sort, but now on the 1<sup>st</sup> element

[(3,2), (4,1), (4,5), (5,4), (5,7), (6,4), (7,1), (7,2), (9,2), (9,3)]

Analysis: there are possibly  $N=9$  digits, and the length of the list is  $n=10$

$O(N + n)$  for the first sort

$O(N + n)$  for the second sort

We can also apply Radix sort to sorting integers

[41, 57, 32, 72, 64, 93, 92, 71, 54, 45]

Max integer in list has 2 digits, so any values with fewer than 2 digits get 0s added to the front.  
Sort the list using Bucket sort on the 2<sup>nd</sup> digit

[41, 71, 32, 72, 92, 93, 64, 54, 45, 57]

Now sort on 1<sup>st</sup> digit

[32, 41, 45, 54, 57, 64, 71, 92, 93]

Analysis: as before,  $N=9$  and  $n = 10$   
 $O(N + n)$  for the first sort  
 $O(N + n)$  for the second sort

A single bucket sort would have had complexity  $O(N+n)$  where  $N$  was 100 (or  $N=61$  if we know the range is 32—93)

Exercise: what algorithm would be best to sort 10000 integers with values from 0 to 100000?

# Sorting: a summary

Bubblesort

Selectionsort

Insertionsort

Heapsort

Mergesort

Quicksort

Bucketsort

# Summary: Bubblesort

Comparison sort

Simple to write, easy to understand, stable, and in-place.

But worst case time complexity is  $O(n^2)$ , and the simple implementation always does the worst case.

In practice, it is slow (slower than other  $O(n^2)$  worst case algorithms), and is almost never used.

# Summary: Selectionsort

Comparison sort.

Reasonably simple to write, easy to understand, in-place.

Normal implementation is not stable.

Worst case time complexity is  $O(n^2)$

In practice, it is slow and rarely used.

# Summary: Insertionsort

Comparison sort.

Reasonably simple to write, easy to understand, in-place and stable.

Worst case time complexity is  $O(n^2)$

It performs well on input that is already close to being sorted.

Can be easily adapted to sort an online stream of incoming data.

Usually better than the other  $O(n^2)$  algorithms, is reasonably fast on smaller inputs, and is often used inside recursive algorithms when the input list gets below a certain size

# Summary: Heapsort

Comparison sort.

Complex to write, requiring a heap data structure

Can be written as an in-place algorithm.

It is not stable.

Worst case time complexity is  $O(n \log n)$

Generally slower in practice than other  $O(n \log n)$  algorithms

# Summary: Mergesort

Comparison sort.

Reasonably easy to write for linked lists, but more complex for a bottom-up array sort.

Difficult to write as in-place

Most implementations are stable.

Worst case time complexity is  $O(n \log n)$

# Summary: Quicksort

Comparison sort.

Basic idea is reasonably simple, but need to be careful when implementing

Can be written as in-place

Not stable.

Worst case time complexity is  $O(n^2)$ ,  
but average complexity is  $O(n \log n)$ , and is normally faster than the  
worst case  $O(n \log n)$  algorithms.

For a long time, thought to be the best practical algorithm.

# Summary: Bucket sort

Distribution sort.

Simple to understand and to implement

Normally implemented to be stable.

Worst case time complexity is  $O(N + n)$ , where  $N$  is the range of the values to be sorted.

Requires  $O(N)$  additional space.

# Summary: Radix sort

Distribution sort.

Essentially multiple iterations of bucket sort on different keys.  
More varieties than discussed here.

Stable.

Worst case time complexity is not clear. Based on number of items in the key words, and number of items.

Not in-place

# Summary: Quicksort

Comparison sort.

Basic idea is reasonably simple, but need to be careful when implementing

Can be written as in-place

Not stable.

Worst case time complexity is  $O(n^2)$ ,  
but average complexity is  $O(n \log n)$ , and is normally faster than the  
worst case  $O(n \log n)$  algorithms.

For a long time, thought to be the best practical algorithm.

?

# Timsort

Specifically designed for Python, by Tim Peters, in 2002.

It is a hybrid of mergesort and insertion sort, designed to perform well when the data is already partially sorted. It is stable.

Timsort:

- finds 'runs' – sequences of items already in sort order
  - merges runs together
  - runs of short length are combined with larger ones using insertion sort
- but is too complex and too detailed to present in this module.

Its worst case complexity is  $O(n \log n)$ , its best case is  $O(n)$ , and it is believed to be faster than Quicksort in most cases.

Now also the default sorting algorithm in Java, and in Android.

The original description to the Python community is here:

<https://svn.python.org/projects/python/trunk/Objects/listsort.txt>

# Sorting: final words

It is important that you understand how the different sorting algorithms work, what their time complexities are, space complexities, and whether or not they are stable.

Sorting is a fundamental skill in computer science and software development, and forms the building blocks for many more complex operations.

But: when you are developing software and programming for real products in well-designed and well-supported languages, you should normally use their built-in sort routines

- they will have been optimised for the language design
